Abstract. *Background/Aim:* The oxazaphosphorines, ifosfamide and cyclophosphamide, represent a class of alkylating agents. The aim of the present *in vitro* study was to compare antileukemic activity of 4-hydroperoxyifosfamide (4-OOH-IF) and 4-hydroperoxycyclophosphamide (4-OOH-CP). *Materials and Methods:* The experiments were performed on MOLT-4 and ML-1 cells. The research was conducted using flow cytometry fluorescein diacetate/propidium iodide (PI), fluorescein-conjugated annexin V/PI, CaspGLOW Red Active Caspase-8 and -9, CellEvent™ Caspase-3/7 Green assays, and tetramethylrhodamine ethyl ester test. *Results:* 4-OOH-IF and 4-OOH-CP distinctly reduced cell viability and triggered apoptosis and necrosis, causing changes in intracellular esterase activity, plasma membrane structure and integrity, caspase activation, and mitochondrial membrane potential. The oxazaphosphorines were responsible for the different antileukemic activities. 4-Hydroperoxyifosfamide appeared to be less cytotoxic against the leukemia cells than 4-hydroperoxycyclophosphamide. MOLT-4 cells were more sensitive to the action of the oxazaphosphorines than ML-1 cells. *Conclusion:* The findings provide a new insight on the mechanisms of cytotoxic action of 4-OOH-IF and 4-OOH-CP on the human acute lymphoblastic and myeloblastic leukemia cells.

*These Authors contributed equally to this study.

Key Words: 4-Hydroperoxyifosfamide, 4-hydroperoxycyclophosphamide, cell viability, cell death, *in vitro* antileukemic activity.

Ifosfamide and cyclophosphamide represent the oxazaphosphorine drugs widely used in clinical practice for their anticancer activity (1-3). Under *in vivo* conditions, both ifosfamide and cyclophosphamide require metabolic activation by specific hepatic cytochrome enzymes to become therapeutically active (2-4). 4-Hydroperoxyifosfamide (4-OOH-IF, D-18851, Figure 1) and 4-hydroperoxycyclophosphamide (4-OOH-CP, D-18864, Figure 1) do not require such metabolic activation in liver and can be applied under *in vitro* conditions (2).

Cell viability and death are two very important parameters that allow assessment of antileukemic activity of different chemical compounds, *e.g.* potential anticancer agents (5, 6). Cell viability is highly dependent on the processes of regulated death which can be initiated by various extracellular and intracellular stimuli (7, 8). Apoptosis and necrosis are two distinct modalities of cell death (9, 10) which can be triggered through the two main pathways, namely the extrinsic/receptor, and intrinsic/mitochondrial pathways (10, 11). Initiator caspase-8 and caspase-9 are important mediators of apoptotic cell death which occurs through the receptor and mitochondrial pathways, respectively, and consequently by executive caspase-3/7 activation (12-15). It is accepted that mitochondria play an essential role during apoptotic and necrotic cell death (16-21). According to the recommendations of the Nomenclature Committee on Cell Death, when investigating cytotoxic agents, quantifiable biochemical parameters, such as plasma membrane structure and integrity, activation of caspases, loss of mitochondrial membrane potential, which accompany regulated cell death induced by such agents, should be determined (8, 10, 11).

The aim of the present study was to compare the *in vitro* antileukemic activity of 4-hydroperoxyifosfamide and 4-hydroperoxycyclophosphamide. The influence of these oxazaphosphorines on cell viability, and apoptotic and

necrotic death was evaluated. After application of these agents, the intracellular esterase activity, plasma membrane impairment, phosphatidylserine externalization, caspase-8, -9, and -3/7 activity, and loss of mitochondrial membrane potential were analyzed.

Materials and Methods

Chemicals. 4-Hydroperoxyifosfamide (D-18851, *cis*-(±)-3-(2-chloroethyl)-2-((2-chloroethyl)amino)tetrahydro-2-oxide-2*H*-1,3,2-oxazaphosphorine-4-yl-hydroperoxide; 4-OOH-IF) and 4-hydroperoxycyclophosphamide (D-18864, *cis*-(±)-2-(bis(2-chloroethyl)amino)tetrahydro-2-oxide-2*H*-1,3,2-oxazaphosphorine-4-yl-hydroperoxide; 4-OOH-CP) (Figure 1) were synthesized at NIOMECH - IIT GmbH (Bielefeld University, Bielefeld, Germany). All solutions were freshly-prepared directly before treatment of cells.

RPMI-1640 medium and fetal calf serum, and Hank's balanced salt solution (HBSS) were obtained from Gibco BRL Life Technologies (Waltham, MA, USA). L-Glutamine, antibiotic antimycotic solution (AAS), and propidium iodide (PI) were purchased from Sigma Aldrich (St. Louis, MO, USA). Fluorescein diacetate (FDA; Sigma Aldrich) and tetramethylrhodamine ethyl ester perchlorate (TMRE; Sigma Aldrich), were kindly provided by the Pavol Jozef Šafárik University in Košice (Košice, Slovakia). *Aqua pro injectione* and 0.9% NaCl were obtained from Polpharma S.A. (Starogard Gdański, Poland), phosphate-buffered saline (PBS) from BioMed (Lublin, Poland), and Hemacolor staining set from Merck KGaA (Darmstadt, Germany). CaspGLOW Red Active Caspase-8 Staining Kit and CaspGLOW Red Active Caspase-9 Staining Kit were purchased from Biovision (Milpitas, CA, USA), and CelleEvent™ Caspase-3/7 Green Flow Cytometry Assay Kit from Molecular Probes (Eugene, OR, USA). Annexin V-FITC Apoptosis Detection Kit were obtained from Becton Dickinson Pharmingen™ (San Diego, CA, USA).

Leukemia cells. Human acute lymphoblastic leukemia MOLT-4 cells and human acute myeloblastic leukemia ML-1 cells were obtained from the European Collection of Cell Cultures (Salisbury, Wiltshire, UK). MOLT-4 and ML-1 cells were cultured in RPMI-1640 medium supplemented with 10% fetal calf serum, 2 mM L-glutamine, and AAS containing 20 units of penicillin, 20 µg streptomycin and 50 ng amphotericin B. The leukemia cells were passaged every third day. MOLT-4 and ML-1 cells were grown at 37°C in an atmosphere of 5% CO₂ in air (HERAcell incubator; KendroLab, Warsaw, Poland). The human acute leukemia cells were seeded in 24-well plates at a density of 15×10⁴ before performing each experiment.

Leukemia cell treatment with oxazaphosphorines. After dilution of the cell suspension to a density of 15×10⁴ cells/ml in complete RPMI-1640 medium, MOLT-4 and ML-1 cells were treated with 4-OOH-IF and 4-OOH-CP. MOLT-4 cells were exposed to the action of 4-OOH-IF and 4-OOH-CP at the doses of 0.5 µg/ml, 1 µg/ml, and 2.5 µg/ml medium, and ML-1 cells were treated with these agents at the doses of 1 µg/ml, 5 µg/ml, and 10 µg/ml medium. The doses of oxazaphosphorines used in the present studies were based on the unpublished data. 4-OOH-IF and 4-OOH-CP were dissolved in *aqua pro injectione* directly before application. The control consisted of untreated MOLT-4 and ML-1 cells.

Figure 1. Chemical structures of 4-hydroperoxyifosfamide (D-18851, 4-OOH-IF) and 4-hydroperoxycyclophosphamide (D-18864, 4-OOH-CP).

Analyses of human leukemia cells exposed to 4-OOH-IF and 4-OOH-CP. The changes occurring in MOLT-4 and ML-1 cells after application of 4-OOH-IF and 4-OOH-CP, were determined using flow cytometry FDA/PI, annexin V-FITC/PI, CaspGLOW Red Active Caspase-8 and -9, CelleEvent™ Caspase-3/7 Green, and TMRE assays.

Flow cytometric FDA/PI assay. Using the FDA/PI assay, FDA is taken up by live cells and hydrolyzed by intracellular esterases, and PI is excluded by an intact cell membrane. Briefly, the leukemia cell suspension containing 5×10⁵ cells was centrifuged for 7 min at 100 × g and 37°C (MPW-351RH centrifuge; Med. Instruments, Warszawa, Poland), and the cell pellet was resuspended in 1 ml of warm HBSS. Then, 10 µl of FDA working solution, at a concentration of 1 µg/ml in HBSS, was added and the leukemia cells were incubated in the dark for 15 min at 37°C. After the incubation with FDA, 20 µl of PI working solution, at a concentration of 30 µg/ml in 0.9% NaCl, was added, and the cells were incubated for additional 5 min. Incubation of cells in the presence of both FDA and PI labeled live cells as green, and cells with impaired plasma membrane integrity as red. Cell samples were placed on ice, away from light, and FDA and PI was immediately measured using flow cytometry (Becton Dickinson, San Jose, CA, USA).

Flow cytometric annexin V-FITC/PI assay. Using Annexin V-FITC Apoptosis Detection Kit, the procedure of dual staining of cells was performed. Briefly, leukemia cell suspension containing 5×10⁵ cells was washed twice with cold PBS, the cells were centrifuged for 7 min at 100 × g and 4°C (MPW-351RH

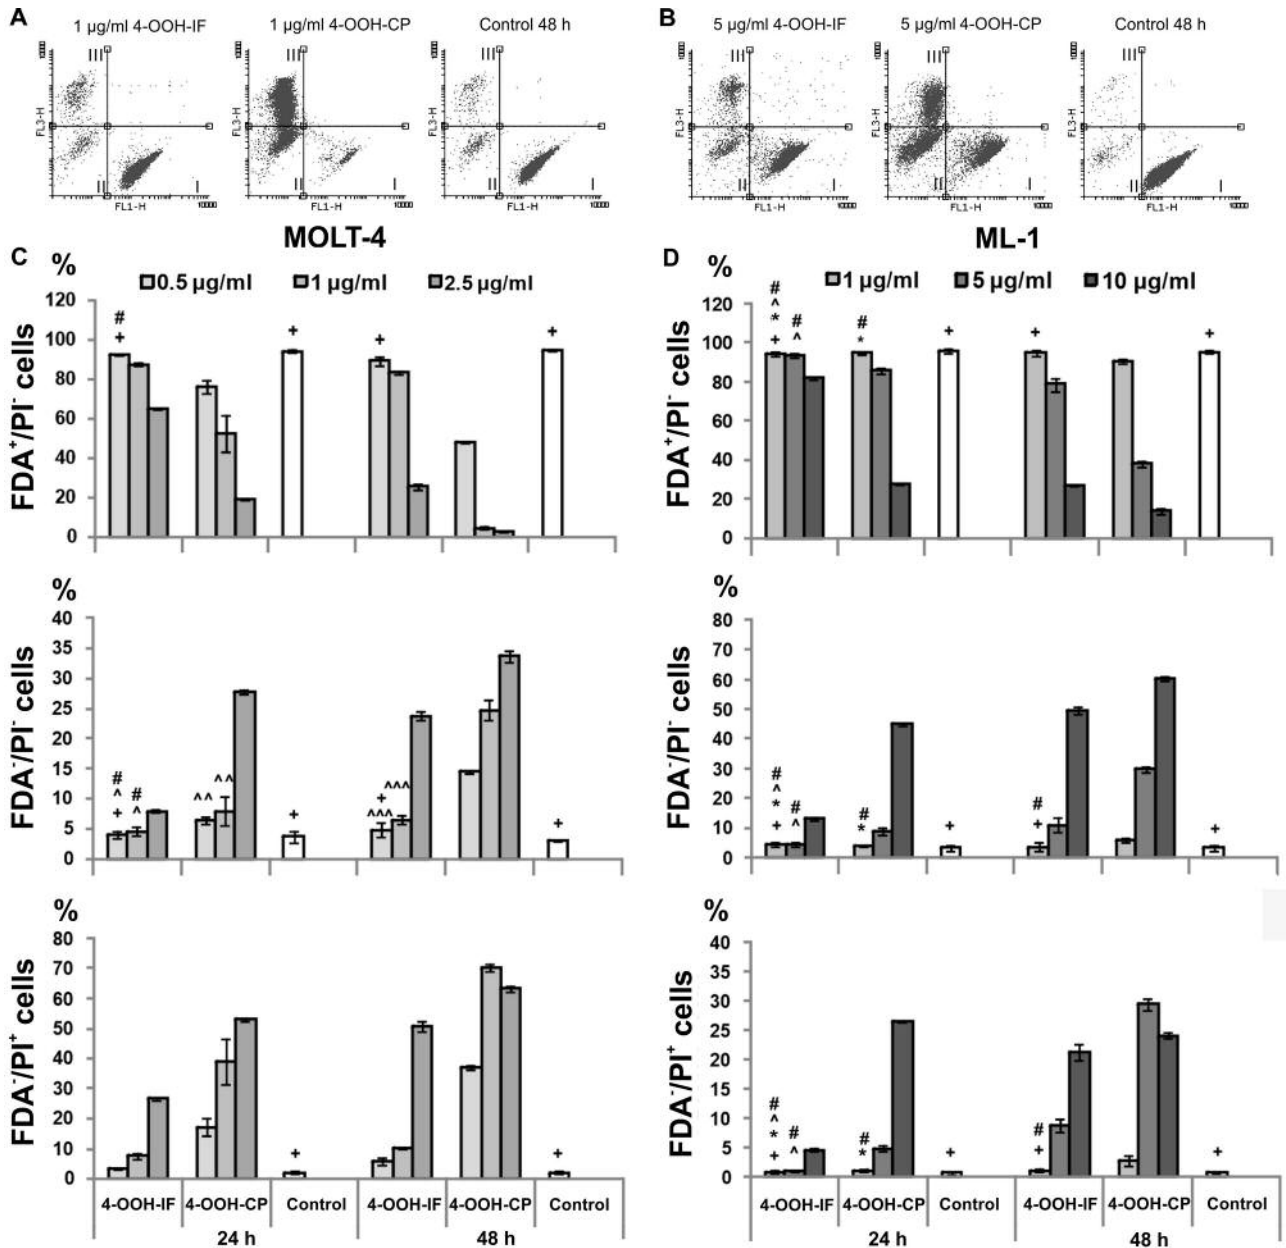

Figure 2. Effects of 4-hydroperoxyifosfamide (4-OOH-IF) and 4-hydroperoxycyclophosphamide (4-OOH-CP) on the viability of MOLT-4 and ML-1 cells determined by flow cytometric fluorescein diacetate (FDA)/propidium iodide (PI) assay. Representative dot plots for MOLT-4 (A) and ML-1 (B) cells stained with FDA (FL1-H) and PI (FL3-H) observed 48 h after application of oxazaphosphorines. Three leukemia cell populations were distinguished: (I) FDA⁺/PI⁻, (II) FDA⁻/PI⁻, and (III) FDA⁻/PI⁺. The percentage values of the different cell populations of MOLT-4 (C) and ML-1 (D) cells were determined 24 h and 48 h after application of 4-OOH-IF and 4-OOH-CP. The obtained data are presented as mean values \pm SD, calculated from three independent experiments carried out in triplicate. Values not significantly different at $p < 0.05$ according to Tukey's multiple range test: #compared to controls; ^between the same agent at different doses; *between agents at the same dose; +between time points.

centrifuge; Med. Instruments), and resuspended in 100 μ l of cold binding buffer. Then 2.5 μ l of annexin V-FITC and 2.5 μ l of PI staining solution were added and the cells were incubated in the dark for 15 min at room temperature. Following the incubation,

400 μ l of binding buffer was added to each tube. Cell samples were placed on ice, away from light, and FITC and PI fluorescence was immediately measured using flow cytometry (Becton Dickinson).

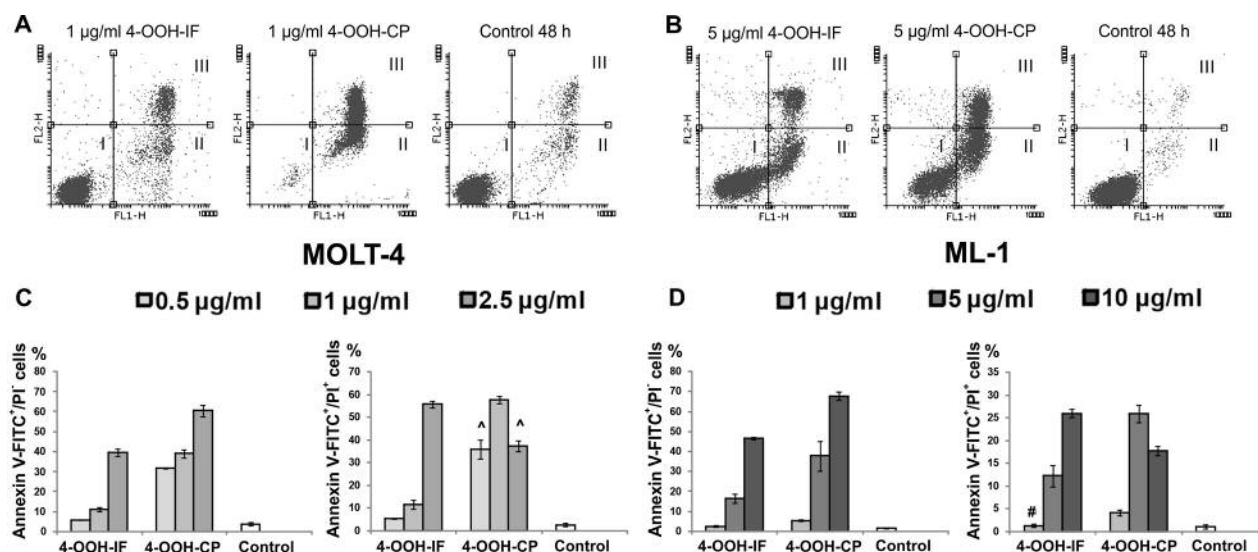

Figure 3. Effects of 4-hydroperoxyifosfamide (4-OOH-IF) and 4-hydroperoxycyclophosphamide (4-OOH-CP) on apoptotic and necrotic death of MOLT-4 and ML-1 cells determined by flow cytometric annexin V-fluorescein isothiocyanate (FITC)/propidium iodide (PI) assay. Representative dot plots for MOLT-4 (A) and ML-1 (B) cells obtained 48 h after application of the oxazaphosphorines; FL1-H: green fluorescence of FITC, FL2-H: red fluorescence of PI. Based on the plasma membrane diversity and impairment, the populations of live cells (I, annexin V-FITC⁻/PI⁻), early apoptotic cells (II, annexin V-FITC⁺/PI⁻), and late apoptotic and necrotic cells (III, annexin V-FITC⁺/PI⁺) were distinguished. The percentage of annexin V-FITC⁺/PI⁻ and annexin V-FITC⁺/PI⁺ MOLT-4 (C) and ML-1 (D) cells was determined 48 h after application of the tested oxazaphosphorine agents. The data are presented as the mean \pm SD calculated from three independent experiments carried out in duplicate. Values not significantly different at $p < 0.05$ according to the Tukey's multiple range test: #compared to controls; ^between the same agent at different doses.

Flow cytometric caspase-8 and -9 assays. Cells were analyzed using CaspGLOW Red Active Caspase-8 Staining Kit and CaspGLOW Red Active Caspase-9 Staining Kit. The fluorescent markers, caspase-8 inhibitor IETD-fluoromethylketone conjugated to sulfo-rhodamine (Red-IETD-FMK), and caspase-9 inhibitor LEHD-fluoromethylketone conjugated to sulfo-rhodamine (Red-LEHD-FMK), irreversibly bind, respectively, to caspase-8 and caspase-9 activated in apoptotic cells. Briefly, the cell suspension was centrifuged for 7 min at $100 \times g$ and 37°C (MPW-351RH; Med. Instruments), and the supernatant was removed by aspiration. The cell pellet was resuspended in 150 μl of PBS, and 0.5 μl of Red-IETD-FMK or 0.5 μl of Red-LEHD-FMK was added into each sample, and the cells were incubated for 1 h at 37°C . Then the cell suspension was centrifuged, the supernatant was removed, and the cells were washed twice in 500 μl of wash buffer. After the washing step, the cells were resuspended in 300 μl of wash buffer, put on ice and analyzed using flow cytometry (Becton Dickinson).

Flow cytometry caspase-3/7 assay. Cells were analyzed using CellEventTM Caspase-3/7 Green Flow Cytometry Assay Kit. CellEventTM Caspase-3/7 Green Detection Reagent, a fluorogenic substrate for activated caspases-3 and -7, consisting of a four-amino acid peptide (DEVD) is conjugated to a nucleic acid-binding dye. After activation of caspase-3/7 in apoptotic cells, DEVD peptide is cleaved, enabling the dye to bind to DNA and producing a bright, fluorogenic response. Briefly, the cell suspension was centrifuged for 7 min at $100 \times g$ and 37°C (MPW 351 RH; Med. Instruments) and the supernatant was removed by aspiration. The cell pellet was

resuspended in 500 μl of PBS. Then 0.5 μl of CellEventTM Caspase-3/7 Green Detection Reagent was added to each sample and the cells were incubated for 30 min at 37°C . After incubation, the leukemia cell samples were analyzed by flow cytometry (Becton Dickinson).

Flow cytometric analysis of mitochondrial membrane potential (MMP). The MMP was analyzed by means of the lipophilic cationic dye TMRE. Retention of TMRE, cell-permeable, positively-charged, red-orange dye, depends on MMP – more greatly polarized mitochondria accumulate more cationic dye, while depolarized mitochondria accumulate less dye. A TMRE stock solution was prepared at a concentration of 10 mM in dimethyl sulfoxide and stored at -20°C . The final concentration of TMRE staining solution used was 100 nM. Briefly, the leukemia cell suspension containing $2.5\text{--}5 \times 10^5$ cells/ml was centrifuged for 7 min at $100 \times g$ and 37°C (MPW-351RH; Med. Instruments). The cell pellet was then washed twice in 1 ml of warm HBSS, resuspended in 100 μl of 100 nM TMRE, and incubated at 37°C in the darkness. After 20-min incubation, the cells were washed with 1 ml of warm HBSS and centrifuged. Next, the supernatant was discarded and the cells were resuspended in 500 μl of HBSS. TMRE fluorescence was immediately detected by flow cytometry (Becton Dickinson).

Statistical evaluation. All flow cytometric data were analyzed using Flowing Software version 2.5.1 (Perttu Terho, Turku Centre of Biotechnology, University of Turku, Finland). The statistical

Figure 4. Flow cytometric analysis of MOLT-4 and ML-1 cells with active caspase-8, -9, and -3/7, conducted 24 h after application of 4-hydroperoxyifosfamide (4-OOH-IF) and 4-hydroperoxycyclophosphamide (4-OOH-CP). Representative histograms of MOLT-4 (A) and ML-1 (B) cells obtained after their exposure to the action of 4-OOH-IF and 4-OOH-CP; H-2: cells with active caspase-3/7; FL1-H: CellEvent™ Caspase-3/7 Green fluorescence. The percentage of MOLT-4 (C) and ML-1 (D) cells with active caspase-8, -9, and -3/7 was determined 24 h after their exposure to the action of 4-OOH-IF and 4-OOH-CP. The data are presented as the mean \pm SD calculated from three independent experiments carried out in duplicate. All data differed significantly at $p < 0.05$ according to Tukey's multiple range test.

significance for the data was evaluated by STATISTICA 10 (StatSoft, Krakow, Poland) using one-way analysis of variance followed by Tukey's honestly significant differences multiple range test. A difference with $p < 0.05$ was considered statistically significant.

Results

The influence of two oxazaphosphorine agents, 4-OOH-IF and 4-OOH-CP, on alterations in the frequency of three leukemia cell populations FDA^+/PI^- , FDA^-/PI^- , and FDA^-/PI^+ (Figure 2), the percentage values of both annexin V-FITC $^+/PI^-$ cells and annexin V-FITC $^+/PI^+$ cells (Figure 3), as well as in the frequency of cells with active caspase-8, -9, and -3/7 (Figure 4) and cells with dissipated MMP (Figure 5) were determined. The cytotoxic activity of the oxazaphosphorines depended on the agent tested, its dose, and the leukemia cell line used (Figures 2-5). 4-OOH-CP reduced leukemia cell viability (Figure 2), triggered apoptotic and necrotic cell death (Figure 3), promoted caspase activity (Figure 4), and caused the loss of MMP (Figure 5) to a higher degree than did 4-OOH-IF. The oxazaphosphorine agents led to weaker cytotoxic effects in ML-1 cells than in MOLT-4 cells (Figure 2-5).

Discussion

In the present study, the *in vitro* cytotoxic activity of 4-OOH-IF and 4-OOH-CP against human acute lymphoblastic leukemia MOLT-4 cells and human acute myeloblastic leukemia ML-1 cells was compared. After application of the oxazaphosphorines, various patterns of changes in intracellular esterase activity, plasma membrane integrity and cell surface exposure of phosphatidylserine, caspase-8, -9, and -3/7 activation, and the MMP were found in MOLT-4 and ML-1 cells. In general, 4-OOH-IF appeared to be less cytotoxic than 4-OOH-CP against the human acute leukemia cells, and MOLT cells were more sensitive than ML-1 cells to the action of both oxazaphosphorine agents.

The mechanisms of action of 4-OOH-IF and 4-OOH-CP depend on their chemical structure and metabolism. The oxazaphosphorine structure is composed of an oxazaphosphorin-2-amine 2-oxide heterocycle containing one atom of phosphorus, one atom of nitrogen and one of oxygen. Ifosfamide and cyclophosphamide have an isomeric structure with one or two 2-chloroethyl groups linked to the nitrogen, respectively (2, 3). In aqueous solution, 4-OOH-IF and 4-OOH-CP spontaneously and rapidly generate 4-

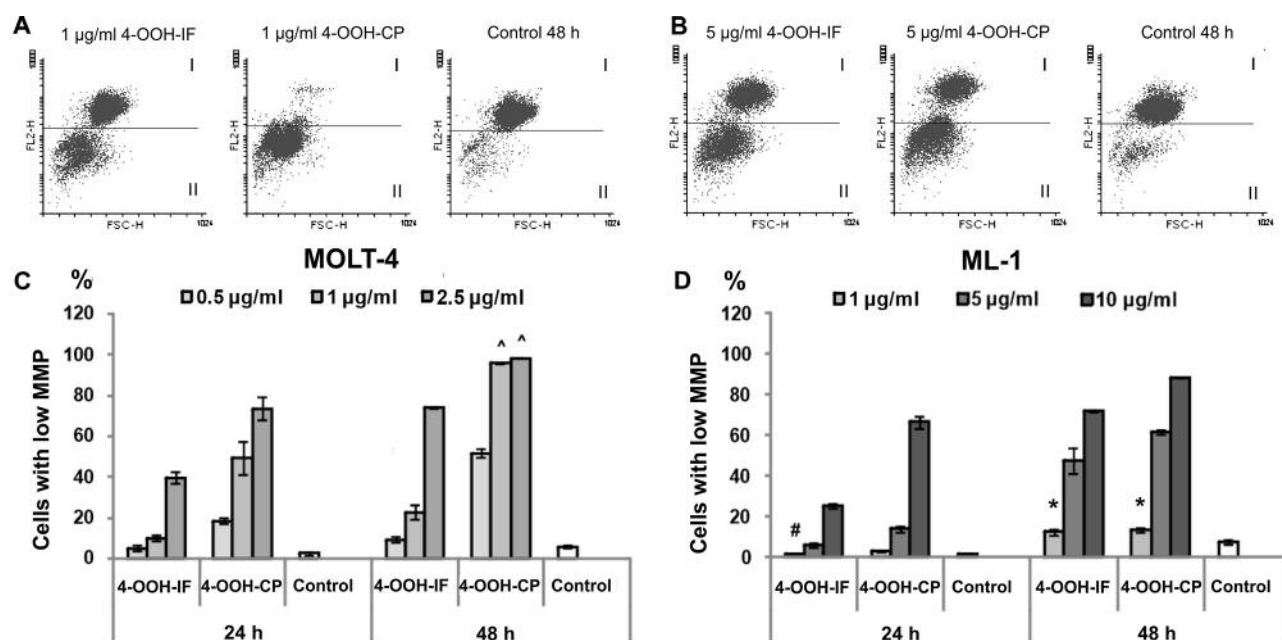

Figure 5. Effects of 4-hydroperoxyifosfamide (4-OOH-IF) and 4-hydroperoxycyclophosphamide (4-OOH-CP) on changes in mitochondrial membrane potential (MMP) of MOLT-4 and ML-1 cells. Representative dot plots for MOLT-4 (A) and ML-1 (B) cells obtained 48 h after their exposure to the action of the two oxazaphosphorines using flow cytometric test; I: cells with high MMP, II: cells with low MMP. The percentage of MOLT-4 (C) and ML-1 (D) cells with low MMP observed 24 h and 48 h after application of the tested oxazaphosphorine agents. The data are presented as the mean \pm SD calculated from three independent experiments carried out in triplicate. Values not significantly different at $p < 0.05$ according to the Tukey's multiple range test: #compared to controls; ^between the same agent at different doses; *between different agents at the same dose.

hydroxyifosfamide (4-OH-IF) and 4-hydroxycyclophosphamide (4-OH-CP), respectively, moreover both agents additionally generate HO-radicals and hydrogen peroxide. 4-OH-IF degrades via aldoifosfamide to ifosfamide mustard and acrolein, while 4-OH-CP degrades via aldophosphamide to phosphoramidate mustard and acrolein. It is accepted that ifosfamide mustard and phosphoramidate mustard are the major reactive alkylating agents of 4-OOH-IF and 4-OOH-CP. The cytotoxic effects of these mustard agents result from intermolecular, alkylation or bisalkylation reactions relating to the intermediate electrophilic aziridiny species. The reactive alkylating compounds are involved in cytotoxic reactions because they can bind to a variety of cellular molecules disturbing normal processes occurring in the cell (1-3).

The present findings indicate that the action of 4-OOH-IF and 4-OOH-CP resulted in induction of apoptosis and necrosis. In human acute leukemia cells undergoing regulated death, 4-OOH-IF and 4-OOH-CP caused plasma membrane impairment and loss of its phospholipid asymmetry by phosphatidylserine externalization, as well as mitochondrial dysfunction. Moreover, these oxazaphosphorines triggered caspase-dependent apoptosis through

the receptor and mitochondrial pathways by caspase-8, -9, and -3/7 cascade activation. These are the first data comparing the regulated cell death-inducing potential of 4-OOH-IF and 4-OOH-CP in human acute lymphoblastic and myeloblastic leukemia cells.

Conclusion

To summarize, the varied responses of MOLT-4 and ML-1 cells to the action of 4-OOH-IF and 4-OOH-CP depend on the chemical structure of the agent and the cell line status. The different *in vitro* antileukemic activities of these oxazaphosphorine agents are associated with their potential for triggering regulated cell death, which is accepted to be one of the mechanisms of cancer therapy. Understanding the processes of regulated cell death induced by oxazaphosphorines is of key importance in chemotherapy.
